Background Information-Context

- Howz is a start-up software company based in Manchester.
- They have designed an award winning home care kit to help people live independently for longer.
- The kit comes with smart sensors which will learn routines within the home by spotting patterns.
- With the app, the household or a carer can track the sensor activity in the house. But the app should also tell you when it detects a change in routine!

Shyam Popat Supervisor: Jess Gillam Meme Lord Sibling: Aastha Popat

Elbow Method

The basic idea behind partitioning methods is to define clusters so that the total intra-cluster variation- within sum of squares WSS- is minimised.

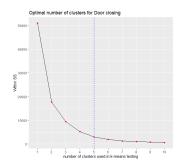

Figure: The data used for WSS is the training data.

글 > : < 글 >

3

Shyam Popat Supervisor: Jess Gillam Meme Lord Sibling: Aastha Popat

Result of clustering

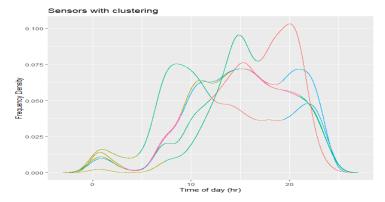

Figure: We can see that usually different peaks have their own clusters.

2

Shyam Popat Supervisor: Jess Gillam Meme Lord Sibling: Aastha Popat Using Point Processes to model Categorical Data

Modeling each cluster.

For each sensor, we want to fit a constant to each of the clusters.

We determine what constant to use by using Maximum Likelihood Estimation.

3 →

э

Shyam Popat Supervisor: Jess Gillam Meme Lord Sibling: Aastha Popat Using Point Processes to model Categorical Data

MLE

The log likelihood for a time in-homogeneous Poisson Process is:

$$\ell(\theta|\mathbf{x}) = -\int_0^T \lambda(x) dx + \sum_{i=1}^n \log(\lambda(x_i)).$$

Suppose we are trying to fit *m* clusters, where cluster *i* ranges from time t_{i-1} to t_i , has k_i observations and an intensity λ_i .

$$= -\lambda_1 t_1 - \lambda_2 (t_2 - t_1) - \dots - \lambda_m (t_m - t_{m-1}) + k_1 \log(\lambda_1) + k_2 \log(\lambda_2) + \dots + k_m \log(\lambda_m).$$

Differentiating wrt $(\lambda_1, \lambda_2, ..., \lambda_n)$, we get for each cluster:

 $\frac{\# \text{ of observations in the time interval}}{\text{length of time interval}}$

Shyam Popat Supervisor: Jess Gillam Meme Lord Sibling: Aastha Popat

Fitting the constant model

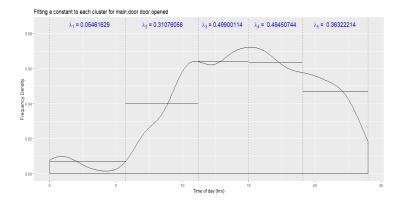

Figure: λ_i represents the per hour frequency in cluster *i*

Further work

There are many avenues I would have liked to explore given more time:

- Modeling clusters with more complicated functions.Hypothesis tests.
- Looking at waiting times between consecutive sensor readings.
- looking at consecutive readings- if the door opens, what can we expect to see next?

- 4 同 6 4 日 6 4 日 6

3

 Modeling clusters with more complicated functions. Making a mixture model where we predict different function with different functions.

Appendix 1: Deriving the MLE:

Suppose that we have a sample $\mathbf{x} = \{x_1, x_2, ..., x_n\}$ that comes from a non-homogeneous Poisson process. The likelihood $L(\lambda | \mathbf{x}) = f(\mathbf{x} | \lambda)$ is the probability of getting the sample $\mathbf{x} = \{x_1, x_2, ..., x_n\}.$

Let $\lambda : [0, T] \to \mathbb{R}_{\geq 0}$ be the intensity function.

$$\Lambda = \int_0^T \lambda(x) dx$$

イロン 不同 とくほう イロン

3

Probability of observing n points = $e^{-\Lambda \frac{\Lambda^n}{n!}}$

Probability density function of observation $x_i = \frac{\lambda(x_i)}{\Lambda}$

Deriving the MLE for a time in-homogeneous Poisson Process Cont.

Independent observations imply

$$P(\mathbf{x}) = \prod_{i=1}^{n} \frac{\lambda(x_i)}{\Lambda}.$$

Likelihood of getting the sample $\mathbf{x} = P(n)P(\mathbf{x}|n)$, i.e.

$$L(\lambda|x) = e^{-\Lambda} \frac{\Lambda^n}{n!} \cdot \prod_{i=1}^n \frac{\lambda(x_i)}{\Lambda}$$

Our sample $x_1 < x_2 < ... < x_n$ is ordered. Then the likelihood of the ordered sample is the above likelihood multiplied by n!.

э

Shyam Popat Supervisor: Jess Gillam Meme Lord Sibling: Aastha Popat

Deriving the MLE for a time in-homogeneous Poisson Process Cont.

$$L(\lambda) = e^{-\Lambda} \cdot \prod_{i=1}^n \lambda(x_i) = e^{-\int_0^T \lambda(x) dx} \cdot \prod_{i=1}^n \lambda(x_i)$$

Therefore the log likelihood is:

$$\ell(heta|\mathbf{x}) = -\int_0^T \lambda(x) dx + \sum_{i=1}^n \log(\lambda(x_i)).$$

э

Shyam Popat Supervisor: Jess Gillam Meme Lord Sibling: Aastha Popat

Appendix 2: Solving for the constant model

Suppose we are trying to fit *m* clusters, where cluster *i* ranges from time t_{i-1} to t_i , has k_i observations and an intensity λ_i .

$$-\int_0^T \lambda(x)dx + \sum_{i=1}^n \log(\lambda(x_i))$$
$$= -\left(\int_0^{t_1} \lambda_1 dx + \int_{t_1}^{t_2} \lambda_2 dx + \dots + \int_{t_{m-1}}^{t_m} \lambda_m dx\right)$$
$$+k_1 \log(\lambda_1) + k_2 \log(\lambda_2) + \dots + k_m \log(\lambda_m).$$

$$= -\lambda_1 t_1 - \lambda_2 (t_2 - t_1) - \dots - \lambda_m (t_m - t_{m-1})$$

+ k_1 log(λ_1) + k_2 log(λ_2) + ... + k_m log(λ_m).

э

Shyam Popat Supervisor: Jess Gillam Meme Lord Sibling: Aastha Popat

Solving for the constant model Cont.

By solving the system

$$\frac{\partial \ell}{\partial \lambda_1} = \frac{\partial \ell}{\partial \lambda_2} = \dots = \frac{\partial \ell}{\partial \lambda_m} = 0$$

We get that for $i \in \{1, ..., m\}$,

$$\hat{\lambda}_i = \left\{ egin{array}{ccc} rac{k_i}{t_i} & ext{if} & i=1, \ rac{k_i}{t_i-t_{i-1}} & ext{if} & i
eq 1, \end{array}
ight.$$

In each case, this is telling us to set the parameter to

 $\frac{\# \text{ of observations in the time interval}}{\text{length of time interval}}$
